

Once we receive a request we use our router to forward the supported requests to the appropriate controller functions. We also use middleware to bridge the gap between our database and the requests. For instance, in our `listings.server.routes.js` we use `router.param` to specify how we will be doing the look up of objects in our controller to our DB. Our controller then utilizes this method to access our database and implement our functions as requested. We access, and obtain the data in our MongoDB, run the according functions on the data and then we throw a response from our controller to the user. .
